This pest risk assessment scheme has been specifically amended from the EPPO Decision-Support Scheme for an Express Pest Risk Analysis document PM 5/5(1) to incorporate the minimum requirements for risk assessment when considering invasive alien plant species under the EU Regulation 1143/2014. Amendments and use are specific to the LIFE Project (LIFE15 PRE FR 001) ‘Mitigating the threat of invasive alien plants to the EU through pest risk analysis to support the Regulation 1143/2014’.
EUROPEAN AND MEDITERRANEAN PLANT PROTECTION ORGANIZATION

Pest risk assessment for *P. stratiotes* L.

This PRA follows EPPO Standard PM5/5 Decision support scheme for an Express Pest Risk Analysis

**PRA area:** EPPO region
**First draft prepared by:** Andreas Hussner
**Location and date:** Paris (FR), 2016-05-23/27

**Composition of the Expert Working Group**

The pest risk assessment for *Pistia stratiotes* has been performed under the LIFE funded project:

LIFE15 PRE FR 001

Mitigating the threat of invasive alien plants to the EU through pest risk analysis to support the Regulation 1143/2014

In partnership with

EUROPEAN AND MEDITERRANEAN PLANT PROTECTION ORGANIZATION

And

NERC CENTRE FOR ECOLOGY AND HYDROLOGY
Review Process

- This PRA on *Pistia stratiotes* was first drafted by Dr Andreas Hussner

- The PRA was evaluated under an expert working group at the EPPO headquarters between 2016-05-23/27.

- Following the finalisation of the document by the expert working group the PRA was peer reviewed by the following:
  
  (1) The EPPO Panel on Invasive Alien Plants (June and July 2016)
  (2) The EPPO PRA Core members (August and September 2016)
  (3) The Scientific Forum on invasive alien species (2017)\(^1\)

Approved by the IAS Scientific Forum on 19/03/2018

---

\(^1\) Additional information has been included in the original document following review from the Scientific Forum on invasive alien species

### Summary of the Express Pest Risk assessment for *P. stratiotes*

**PRA area:** EPPO region (see https://www.eppo.int/ABOUT_EPPO/images/clickable_map.htm.)

**Describe the endangered area:** The endangered area is the Mediterranean biogeographical region (EU Member States: France, Greece, Italy, Portugal, Spain; wider EPPO region: Albania, Algeria, Turkey, Morocco, Tunisia).

Climate modelling suggests that the species is also capable of establishment in small areas of the Black Sea and Atlantic biogeographical regions. The southern countries within the EPPO region provide suitable climatic conditions for *P. stratiotes*. All water bodies not enclosed in ice during the winter months, including thermally abnormal waters in other EPPO countries, provide potential habitats for *P. stratiotes*.

*Pistia stratiotes* has already been reported as a casual occurrence in Austria, Belgium, Croatia, Czech Republic, parts of France, Germany, Hungary, Italy, The Netherlands, Norway, Portugal, Romania, Russia, Slovenia, Spain and the United Kingdom. In addition, the species is established in Morocco, and Israel and in at least one location along the Rhône river in the south of France. The species is established in Germany, Russia and Slovenia in thermal waters.

**Main conclusions**

*Pistia stratiotes* presents a high phytosanitary risk for the endangered area within the EPPO region with a low uncertainty. Further spread within and between countries is likely. The overall likelihood of *P. stratiotes* continuing to enter the EPPO region is high because the species is widely cultivated and continuously traded within the EPPO region.

The risk of the species establishing in other EPPO countries is considered high as the plant is widely traded. However, the species is already banned from trade in Spain and Portugal.

Potential spread as movement through irrigation and river systems may act to facilitate spread nationally and regionally. The potential high impact of the species within the EPPO region should be considered similar to that seen in other regions where the species has established and become invasive; i.e. Australia, Africa and the Southern States of the USA.

Based on evidence elsewhere in the world, important ecosystem services are likely to be adversely affected by the presence of the plant. Impacts are likely to be more pronounced in countries and regions where the climate is most suited to establishment, growth and spread.

**Entry and establishment**

*Pistia stratiotes* is imported into the EPPO region. The species is already present and established within the PRA area – Morocco, Israel, France, Germany, Slovenia and Russia, in the case of the three latter, in thermal waters. The overall likelihood of *P. stratiotes* entering the EPPO region is high. As the species reproduces sexually, local adaptation is possible.

The pathways identified are:
- Plants for planting (high likelihood)
- Contaminant of plants for planting (low likelihood)
- Contaminant of leisure equipment (low likelihood)

*Pistia stratiotes* may establish throughout climatically suitable aquatic habitats within the EPPO region. *P. stratiotes* is tolerant of a wide range of environmental aquatic conditions. Frost will...
limit the northern and eastern distribution of this species. Climate change could increase the likelihood of establishment, spread and impact in more areas of the EPPO region.

**Potential impacts in the PRA area**

Impacts in the EPPO area will of course likely be attenuated by climatic suitability, but, in areas where *P. stratiotes* will overwinter and spread, impacts are likely to be similar. For example, many of the impacts on biodiversity relate to ecosystem processes such as decomposition and the alteration of nutrient cycling, which, assuming that *P. stratiotes* is able to reach the levels of abundance required for these impacts to be displayed, this can be assumed to occur in these areas just as much as in the current area of distribution. Like other floating mats forming plants, impacts on flora and fauna are likely due to the shading and the prevention of wind induced mixing of the water column, which can result in anoxic conditions.

Aquatic free-floating plants are highly opportunistic and have the ability to exploit novel habitats. Other non-native mat forming species have been shown to have high impacts in the PRA area. Ecological impacts occur within the PRA area on flora and fauna, specifically documented for the former in the River Erft in Germany, where floating mats shade out native submerged vegetation.

The potential economic impact of *P. stratiotes* in the EPPO region could be significant if the species spreads and establishes in further areas. There is potential for the species to impede transport and affect recreation, irrigation and drainage. Based on experience elsewhere in the world, management is likely to be both expensive and difficult. There are no indigenous host specific natural enemies in the EPPO region to regulate the pest species, and in many EPPO countries herbicide application in or around water bodies is highly regulated or not permitted.

Even though the EWG considers the magnitude of impacts will be similar to that seen in the current area of distribution, the uncertainty will increase for all categories (impact on biodiversity, impact on ecosystem services and socio-economic impact). This is mainly due to the fact that impacts have not been measured in the PRA area.

In the PRA area, *P. stratiotes* has the potential to impact on native plant species due to its invasive smothering behaviour. The invasion of alien invasive plants can increase competition for space with native aquatic plants and this will affect the most threatened aquatic plant species (Bilz et al., 2011).

In areas where *P. stratiotes* is unable to establish all year round, negative impacts may still be seen in the summer months, including impacts on ecosystem services (cultural: restricting access for recreation and tourism, and supporting: altering the chemical composition of the water column) (EWG opinion). Furthermore, seasonal cover on the waterbody can act to displace native plant species (EWG opinion).

Potential red list species and species from the Habitat Directive which may be impacted on both under current climate and future climate include *Isoetes malinverniana* (Critically Endangered, Italy), *Elatine brochonii* (Vulnerable, France and Spain), *Anagallis crassifolia* and *Marsilea strigosa* (Vulnerable, France, Italy and the Iberian Peninsula), *Pilularia minuta* (Endangered), *Damasonium polyspermum* and *Ipomoea sagittata* (Vulnerable).

Within the EPPO region, *P. stratiotes* can negatively impact on freshwater bodies such as canals, rivers (slow moving), ponds, irrigation channels, estuaries, reservoirs and lakes. Many freshwater bodies and wetland sites are protected within the EPPO region. Freshwater habitats are detailed within the Habitats Directive 1992 and the Water Framework Directive 2000. Such habitats often harbour rare or endangered species. Protected sites potentially impacted on are detailed in section 7.
Dense mats of *P. stratiotes* can provide a suitable habitat for disease-carrying mosquitoes which may have impacts on human health (EWG opinion).

The text within this section relates equally to EU Member States and non-EU Member States in the EPPO region.

Successful on-going control of *P. stratiotes* is underway in Morocco using the classical biological control agent *Neohydronomus affinis* combined with manual removal.

**Climate change**

By the 2070s, under climate change scenario RCP8.5, the projected suitability for *P. stratiotes* in Europe and the Mediterranean increased substantially. The model suggested that in this climate, much of Mediterranean, western and Pannonian Europe could become suitable for invasion, and suitability also increases around the coasts of the Black Sea and Caspian Sea. Therefore, the model suggests climate change could facilitate a major expansion of the species in Europe. Countries suitable include Portugal, Spain, France, Italy, Greece, Belgium, Netherlands, Slovenia, Croatia, Turkey, Bulgaria, Germany, Russia (coast of the Black Sea), Algeria, Morocco, Tunisia.

**Phytosanitary measures:**

The results of this PRA show that *P. stratiotes* poses an unacceptable risk to the endangered area (Mediterranean biogeographical region) with a moderate uncertainty.

**Other recommendations:**

**Inform EPPO or IPPC or EU**
- Inform NPPOs, that surveys are needed to confirm the distribution of the plant, in particular in the area where the plant is present; and on the priority to eradicate the species from the invaded area.

**Inform industry, other stakeholders**
- Encourage industry to assist with public education campaigns associated with the risk of aquatic non-native plants.

**Specify if surveys are recommended to confirm the pest status**
- Surveys should be conducted to confirm the current distribution and status of the species within the endangered area and this information should be shared within the PRA area.
Express Pest Risk assessment: P. stratiotes L.

First draft prepared by: Dr. Andreas Hussner, Jackels Umweltdienste GmbH, Siemensring 9, 41334 Nettetal

Date: 2016-05-03

Stage 1. Initiation

Reason for performing the PRA:

Pistia stratiotes currently has a limited distribution within the natural environment in the EPPO region. In Europe, P. stratiotes has been found in Belgium, Croatia, Czech Republic, France, Germany, Hungary, Italy, The Netherlands, Portugal, Romania, Russia, Slovenia and Spain (Diekjobst, 1984; Mennema, 1977; Brundu et al., 2012; Pilipenko, 1993; Garcia Murillo, 2005; Sajna et al., 2007; Verloove, 2006). Hussner 2012, EPPO 2012; Boršić & Rubinić, 2018). Further spread is predicted as the species is traded and used in aquaria and ponds within the EPPO region. Due to the frost sensitivity of the species, it can only become established in waters which are not covered by ice during winter months. Consequently, large infestations of the species have only been reported for the southern parts of the EPPO region and for thermal waters in Germany, Slovenia, and Russia (Sajna et al. 2007, Brundu et al. 2012, Hussner et al. 2014a). The dense mats of P. stratiotes block sunlight which limits the growth of submerged plant species and prevents wind induced mixing of the water column causing reductions in dissolved oxygen that may result in anoxia with serious effects on fish and invertebrate species (Hussner et al., 2014a). The plant also increases evapotranspiration resulting in water loss. The presence of the species in the EPPO region, and the continued availability of this plant for purchase within EPPO countries, coupled with a warming climate, mean that a PRA is required. In 2016, the species was prioritized (along with 36 additional species from the EPPO List of Invasive Alien Plants and a recent horizon scanning study) for PRA within the LIFE funded project “Mitigating the threat of invasive alien plants to the EU through pest risk analysis to support the Regulation 1143/2014”. P. stratiotes was one of 16 species identified as having a high priority for PRA.

PRA area:
The EPPO region (see https://www.eppo.int/ABOUT_EPP0/images/clickable_map.htm.)

Stage 2. Pest risk assessment

1. Taxonomy: P. stratiotes L. (Kingdom Plantae; Phylum Tracheophyta; Class Liliopsida; Order: Arales; Family Araceae; Genus Pistia) according to IUCN, APHI [http://www.mobot.org/MOBOT/research/APweb/].

Domain: Eukaryota ; Kingdom: Plantae; Phylum: Spermatophyta; Subphylum: Angiospermae; Class: Monocotyledonae, Order: Arales according to CABI

EPPO Code: PIIST

**Common names:** water lettuce, tropical duckweed, Nile cabbage

**German name:** Muschelblume, Wassersalat, **French name:** Laitue d'eau, pistie, **Spanish name:** Lechuguilla de agua, lechuguita de agua, repollo de agua, **Dutch name:** watersla, Mosselplant.

**Plant type:** Perennial floating aquatic macrophyte

**Related species in the EPPO region:** none

### 2. Pest overview

**Introduction**

*Pistia stratiotes* is a free floating aquatic plant. The native range of the species is not clear, but it is suggested, that the species is either native to South America (Neuenschwander et al. 2009), or that *P. stratiotes* is a pan-tropical species occupying a native range across the tropical and subtropical regions of Asia, Africa, Australia and South America (Gillett et al., 1988; Evans 2013). However, other studies suggest that the species has a palearctic origin (Renner & Zhang, 2004). In the USA, there is some uncertainty to whether the species is native to Florida, while it was described for the first time in 1765 from William Bartram (https://plants.ifas.ufl.edu/plant-directory/pistia-stratiotes/#1). Regardless of this, the species is considered a management priority. The species is present in Africa, Asia, Europe, North America and Oceania (Neuenschwander et al. 2009), and appears in the list of the world’s worst weeds (Holm et al., 1977). The species is sold as an ornamental aquatic plant in the PRA area. *P. stratiotes* was added to the EPPO Alert List in 2007 and subsequently transferred to the List of Invasive Alien Plants in 2012. Within the EPPO region the species has the capacity to become established in the Mediterranean region and in thermal water bodies. In addition, species distribution models suggest that the endangered area is the Mediterranean biogeographical region (see appendix 1, Figure 5 and Appendix 2, Figure 1). Southern countries within the EPPO region currently provide suitable climatic conditions for the plant. This includes at least all regions, in which the water bodies are not enclosed in ice during the winter months. The suitable area is likely to increase under likely scenarios of climate change (e.g. Hallstan, 2005).

**Environmental requirements**

*Pistia stratiotes* grows in slow moving rivers and reservoirs, irrigation channels, ponds, lakes, canals and ditches (Cilliers 1991, Venema 2001, Adebayo et al. 2011, Hussner et al. 2014a). *P. stratiotes* can grow under varying physical and chemical conditions. Its growth is optimal at temperatures between 22-30 °C and high nutrient conditions (Pieterse et al., 1981, Henry- Silva et al. 2008). However, plants still develop at temperatures as low as > 10 °C (Hussner et al., 2014a, Pieterse et al., 1981). The plants are susceptible to low temperatures and frost and die back when enclosed in ice and at temperatures slightly above 0 °C (MacIsaac et al., 2016) (Appendix 3; Figure 1). *P. stratiotes* can withstand freezing air temperatures as the small floating form, as long as the leaves are in direct contact with the water surface in water temperatures >10 °C (Hussner et al., 2014) (Appendix 3; Figure 2). Seeds of *P. stratiotes* germinate at a lower temperature limit of 20 °C, are resistant to frost and can withstand temperatures of -5 °C, however, germination rates decrease with a prolonged frost period (Pieterse et al., 1981, Kan & Song, 2008, Hussner et al., 2014a, Kurugundla, 2014). *P.
Stratiotes was found to be tolerant to salt and can withstand 200 mmol/l NaCl in the water (6 PSU) (Upadhyay and Panda, 2005).

Habitats

Pistia stratiotes grows in aquatic habitats such as lakes, canals, reservoirs and slow moving rivers. The species often invades rice paddies in Asia as well as other wetland habitats. The species can survive drying, and can reinfest ephemeral waters which are subject to seasonal drying, because of seed survival and germination. See also the Environmental requirement section above.

Identification

Pistia stratiotes is a free floating plant with a rosette of obovate to spatulate, short haired leaves (up to 40 cm in length in African forms and up to 35 cm in European forms (Neuenschwander et al., 2009, Hussner unpublished)) (Appendix 3; Figure 3). P. stratiotes is a clonal plant that forms small colonies with daughter plants attached to the mother plant through stolons. Dispersal is enhanced through detachment of daughter plants which form new colonies. The upper sides of the leaves are light-green, while the undersides are almost white. The floating plants have a large feathery root systems which hangs freely in the water (Appendix 3; Figure 3). The solitary inflorescence is axillary and inconspicuous, with short peduncles in the center of the rosette. The spadix, with a single pistillate flower and several staminate flowers enclosed in a whitish spathe, is pale green, hairy outside and glabrous inside (Neuenschwander et al., 2009; Buzgo 2015, http://www.aroid.org/genera/pistia/buzgopistia.php). The peduncle bends after fertilization and pushes the fruits underwater where up to 30 seeds per fruit can be released (Neuenschwander et al., 2009; Kurugundla, 2014) (Appendix 3; Figure 4).

Flowering plants are widely observed within the EPPO region and the plants produce numerous viable seeds (Hussner et al., 2014a).

Symptoms

Pistia stratiotes forms dense mats at the surface of the water body reducing light penetration, which reduces suitable habitats for native submerged plants (Appendix 3; Figure 5 & 6). Additionally, P. stratiotes reduces wind induced mixing of the water column, which decreases the levels of dissolved oxygen, sometimes resulting in anoxia, decreases pH, increases the CO2 concentration and reinforces stratification. Overall, this results in a reduction of native macrophytes, macroinvertebrates and fish species (Attionu, 1976; Sridhar & Sharma, 1980; Sajna et al., 2007). P. stratiotes produces allelochemicals against algae (Aliotta et al., 1991), thus if shading is not sufficient then additional effects on algae growth in infested waters are likely. The changes in hydrochemistry reduce the water quality, especially for its use as drinking water (Neuenschwander et al., 2009). In addition, the mat forming habit can result in the clogging of water bodies and this is likely to obstruct access for water based recreational activities.

Pistia stratiotes mats clog waterways and limit the recreational use of water bodies, reduce the efficiency of irrigation and drainage systems and increase water loss due to evapotranspiration (Tripathi et al., 2010). Moreover, dense mats of P. stratiotes reduce water flow and can damage flood control structures. Moving mats of P. stratiotes can form blockages against bridges and reduce hydropower generation (Howard and Harley, 1998). In areas of high wave action, mats of P. stratiotes can physically damage rooted aquatic plants in shallow waters.

Pistia stratiotes mats serve as preferred host sites for the larvae of several mosquito species (Holm et al., 1969). These include Anopheles and Mansonia, which act as vectors for malaria (Lounibos & Dewald, 1989; Rejmankova et al., 1991; Parsons & Cuthbertson, 2001).
Existing PRAs for *P. stratiotes*

Pacific Island Ecosystems at Risk (PIER): This risk assessment predicts the likelihood of invasiveness of the species in Australia, Hawaii and the high islands of the Pacific, and in the State of Florida. The PRA was prepared for Australia and scored *P. stratiotes* with 18 indicating that the species poses a high risk of becoming a serious pest.

New Zealand (Aquatic Weed Risk Assessment Model, AWRAM): In a risk assessment for New Zealand, *P. stratiotes* received a score 42 out of 100 points, indicating the species has a moderate weed potential (Champion *et al.*, 2007).

Europe: This PRA is being conducted under the LIFE project (LIFE15 PRE FR 001) within the context of European Union regulation 1143/2014, which requires that a list of invasive alien species (IAS) be drawn up to support future early warning systems, control and eradication of IAS.

Ireland: *P. stratiotes* is considered to have only a minor overall risk of becoming invasive in Ireland (Millane & Caffrey, 2014).

Socio-economic benefits

*Pistia stratiotes* is widely sold as an ornamental species within the EPPO region, including EU Member States. The species is also sold/exchanged between aquarists. The species regularly features on aquatic plant websites and online retailers. For example aquabase, amazon and other specialist suppliers:

https://www.amazon.co.uk/Lettuce-Pistia-Stratiotes-Aquarium-Floating/dp/B00CPUXE2O
http://www.lilieswatergardens.co.uk/pistia-stratiotes-british-grown-raised-loose-plants-p-1315.html

The Ornamental Aquatic Trade Association (UK based) carried out a survey with its members in August 2016 requesting advise on the number of plants and value that they had sold in the calendar year for 2015. Thirty-three members responded to this survey and detailed that in total 27 982 *P. stratiotes* plants were sold in the UK in 2015 with a value of GBP 101 133.

According to van der Valk *et al.* (2018), there are 5 to 10 businesses that grow *Pistia stratiotes* in the Netherlands, mainly for export. The total trade value of *Pistia stratiotes* in the Netherlands is estimated to be between 0.5 and 1 million euro/year.

*Pistia stratiotes* is widely used for phyto remediation of metals (Aurangzeb *et al.*, 2014; Farnese *et al.*, 2014), chemical products (hepatotoxin: Somdee *et al.*, 2016), oil (Yang *et al.*, 2014), removal of pharmaceuticals and personal care products (Lin & Li, 2016) or for urban sewage treatment (Zimmels *et al.*, 2006). *P. stratiotes* biomass can be used for bioethanol production, with ethanol yields per unit biomass comparable to other agricultural biomasses (Mishima *et al.*, 2008), and biogas production (Abassi & Nipaney, 1991). However, the implementation of this is unlikely to be economically viable based on experiences in Uganda and elsewhere (Personal Communication, Martin Hill, 2016).

The fiber content, carbohydrate and crude protein content of *P. stratiotes* is comparable to quality forages (Parsons & Cuthbertson, 2001). While cows find *P. stratiotes* unpalatable, the plants can be fed to pigs (Nonindigenous Aquatic Species Database, 2015). *P. stratiotes* is also used for Ayurvedic medicine and used for its diuretic, antidiabetic, antidermatophytic, antifungal and antimicrobial properties (Tripathi *et al.*, 2010).

*Pistia stratiotes* is used as a soil conditioner in rice where it improves crop yield (Roger *et al.*, 1984).
Apart from being sold in the EPPO region, none of the other detailed benefits have been utilised in the region.

3. Is the pest a vector?  
No

4. Is a vector needed for pest entry or spread?  
No

No vector is needed for *P. stratiotes* spread or entry into the PRA area.

5. Regulatory status of the pest

**Europe (overall):** *Pistia stratiotes* was evaluated through the EPPO prioritisation scheme in 2016, and was considered to be a high priority for a PRA given its potential for further spread within the EPPO area, and the fact that cost-effective control may be possible through trade restrictions. The species has been on the EPPO “List of Alien Invasive Plants” since 2012; prior to that it was on the EPPO “Alert List” from 2007. *P. stratiotes* was also assessed under an all-taxa horizon scanning exercise designed to help prioritise risk assessments for the “most threatening new and emerging invasive alien species” in Europe (Roy *et al*., 2015); however, *P. stratiotes* was not included on the final list produced by that project.

**Netherlands:** a Code of Conduct recommended that the sale of *P. stratiotes* is only allowed when additional information is provided on a label. The warning label must inform customers about the potential invasion risk of the species to reduce the risk of release into the wild (Verbrugge *et al*., 2014).

**Germany:** *Pistia stratiotes* has been listed as a potentially invasive plant (Nehring & Hussner 2013) and it is recommended not to trade the species by the Federal Agency for Nature Conservation, Germany (Schmiedel *et al*., 2015).

**Spain:** In Spain, the species is included in the list of the prohibited species of the Real Decreto 630/2013 [http://www.boe.es/boe/dias/2013/08/03/pdfs/BOE-A-2013-8565.pdf](http://www.boe.es/boe/dias/2013/08/03/pdfs/BOE-A-2013-8565.pdf).

**North America:** *P. stratiotes* is listed as an alien species in Alabama (class C, noxious weed), California (B list, noxious weed), Connecticut (potentially invasive, banned), Florida (prohibited aquatic plant, Class 2), South Carolina (invasive aquatic plant) and Texas (noxious plant) (USDA, 2015).

**New Zealand:** *Pistia stratiotes* is legally prohibited from sale (Champion *et al*., 2014).

**Japan:** *Pistia stratiotes* is subject to legal control [https://www.nies.go.jp/biodiversity/invasive/DB/etoc8_plants.html](https://www.nies.go.jp/biodiversity/invasive/DB/etoc8_plants.html)

**South Africa:** In South Africa control of the species is enabled by the Conservation of Agricultural Resources (CARA) Act 43 of 1983, as amended, in conjunction with the National Environmental Management: Biodiversity (NEMBA) Act 10 of 2004. *P. stratiotes* was specifically defined as a Category 1b “invader species” on the NEMBA mandated list of 2014 (Government of the Republic of South Africa, 2014). Category 1b means that the invasive species “must be controlled and wherever possible, removed and destroyed. Any form of trade or planting is strictly prohibited” ([www.environment.gov.za](http://www.environment.gov.za)).

**Introduction:**

*Pistia stratiotes* has a pan-tropical and subtropical distribution. See Appendix 4 Figure 1.

**Africa**

*Pistia stratiotes* is widespread throughout Africa. In South Africa, the plant is recorded as invasive, the first record was in 1865 from KwaZulu-Natal (Hill, 2003). *P. stratiotes* was first recorded on a small multipurpose impoundment near the town of Fez in Morocco in 2012 (Hill, 2013). See Appendix 4 Figure 2 for the distribution of the species in Africa.

**Asia**

In Asia, *P. stratiotes* has a wide distribution and is recorded as invasive (CABI, 2016). See Appendix 4 Figure 3 for the distribution of the species in Asia. The plant was recorded in the Philippines as early as 1925, floating in abundance in shallow waters (Merrill and Elmer, 1925; Waterhouse, 1997).

**North America:**

*Pistia stratiotes* occurs in several states of the USA. It is generally considered as an introduced plant species and classified as a pest species and under regulation in some states (see section 5). There are casual records from the Great Lakes (Adebayo et al., 2011). See Appendix 4 Figure 4 for the distribution of the species in North America (see also Figure 5 for the distribution in South America).

**Oceania:**

*Pistia stratiotes* is widespread in the Northern Territory in Australia. The species was eradicated from New Zealand (North Island). *P. stratiotes* is invasive in Papua New Guinea and first
recorded in 1971 (Forman, 1971). See Appendix 4 Figure 6 for the distribution of the species in Oceania.

**Europe**

*Pistia stratiotes* has been reported for: Austria (Neuenschwander *et al.* 2009), Belgium (Verloove, 2006), Croatia (Boričić & Rubinić, 2018), Czech Republic, France (Fried, 2012), Germany (Nehring & Hussner 2013 *et al.*, 2015), Hungary, Italy (Brundu *et al.*, 2012), Netherlands (Mennema 1977), Norway (ARTSDATABANKEN, 2016), Portugal, Romania, Russia (Schanzer *et al.*, 2003), Slovenia (Sajna *et al.*, 2007), Spain and the United Kingdom (Somerset Rare Plants Group, 2010). See Appendix 4 Figure 4 for the distribution of the species in Europe. *P. stratiotes* was found for the first time in the Netherlands in 1973 but the plants did not become established (Mennema 1977). First reports from Austria and Germany were made in 1980 (Schmiedel *et al.*, 2015). Repeated introductions failed to establish in Germany up until 2005, however, since 2008, an established population has been permanently present in thermal sections of the River Erft (Hussner *et al.*, 2014a). In Italy, *P. stratiotes* was found first in 1998 (Brundu *et al.*, 2012). In France, *P. stratiotes* was found once in the Landes department in 2003, but is no longer present (EPPO 2012). Several casual populations have also been recorded in the Mediterranean parts of France since 1998 (SILENE, 2016) and an established population occurs in at least one location (where the first observation date back to 2005) in a canal along the Rhône river (Fried, com. pers., update 2016) (see Fig. 8 & 9, Appendix 3). In 2012, a first management action has been undertaken due to the high density reached by *P. stratiotes* colonies at the end of the summer. In September 2016, *P. stratiotes* has been recorded all along 17 km of the canal, including several portions with 100% cover, one of them on about 1 km of the canal. In Slovenia, an established population has been documented from a thermal river (Sajna *et al.*, 2007). In Belgium, the species was first observed in 2000, and is still present in 2015 mainly in East Flanders (Verloove, 2006, update 2015). In Russia, *P. stratiotes* is known from some ponds and rivers around Moscow (Schanzer *et al.*, 2003). *P. stratiotes* was found in Spain (García Murillo, 2005), though the species is no longer present on the mainland. On the Canary Islands, the species is considered invasive. In the United Kingdom, the species has been recorded around 45 times; four of these occurrences are detailed as persisting for more than five years in the database of the Botanical Society of Britain and Ireland. However, it is not clear if all occurrences still remain. *P. stratiotes* was first discovered in Somerset (United Kingdom) in 2004, when a few plants were discovered on the Burnham Level. The plant is now “well established” in Bridgwater and Taunton Canal (United Kingdom) (Somerset Rare Plant Group Newsletter, 2010). However, (Natural History Reports, 2009) mention that the species may be planted in the area and that the plants are close to houses where *Eichhornia crassipes* was also observed growing. Potentially, these non-native plants are released locally at regular interval or propagules are overwintering in protected microclimates along the bank of the river or manmade structures. See Appendix 4 Figure 7 for the distribution of the species in Europe.

</tr>
</tbody>
</table>

*Pistia stratiotes* grows in aquatic habitats such as lakes, canals, reservoirs and slow moving rivers. The species often invades rice paddies in Asia as well as other wetland habitats. The species can survive drying, and can reinfect ephemeral waters which are subject to seasonal drying, because of seed survival and germination.

Many freshwater bodies and wetland sites are protected within the EPPO region. Freshwater habitats are detailed within the Habitats Directive 1992 and the Water Framework Directive 2000. Such habitats often harbour rare or endangered species.
## 8. Pathways for entry (in order of importance)

| Possible pathways | Pathway: Plants for planting  
(CBD terminology: Escape from confinement) |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Short description explaining why it is considered as a pathway</td>
<td><em>P. stratiotes</em> is imported into the EPPO region from outside and plants are widely sold within the EPPO region as an ornamental plant for ponds and aquaria. Brunel (2009) reports that more than 3600 individual plants were imported into the EPPO region (mainly into France), though the period of these imports is not specified. The Ornamental Aquatic Trade Association (UK based) carried out a survey with its members in August 2016 requesting advise on the number of plants and value that they had sold in the calendar year for 2015. Thirty-three members responded to this survey and detailed that in total 27 982 <em>P. stratiotes</em> plants were sold in the UK in 2015 with a value of GBP 101 133.</td>
</tr>
<tr>
<td>Has the pest already been intercepted on the pathway?</td>
<td>Yes because it is the commodity itself.</td>
</tr>
<tr>
<td>What is the most likely stage associated with the pathway?</td>
<td>Live plants both large and small, including seedlings (Appendix 3; Figure 7, will be associated with this pathway.</td>
</tr>
<tr>
<td>What are the important factors for association with the pathway?</td>
<td><em>P. stratiotes</em> was found to be widely sold in shops in Germany (Hussner <em>et al.</em>, 2014b), and additionally it is frequently sold in online marketplaces such as ebay (<a href="http://www.ebay.com">www.ebay.com</a>).</td>
</tr>
<tr>
<td>Is the pest likely to survive transport and storage in this pathway?</td>
<td>Yes. As an import for ornamental purposes, care would be taken to ensure plants survive during transportation.</td>
</tr>
<tr>
<td>Can the pest transfer from this pathway to a suitable habitat?</td>
<td>Only through human agency (i.e. intentional introductions or the unintentional disposal of plants into wild habitats). The species could be misused and introduced directly into freshwater bodies and ecosystems (e.g. stream, lakes, dams). The unintended habitats are freshwater bodies and ecosystems (semi-natural and natural waterbodies). Plants used in confined waterbodies could spread to unintended habitats very easily through human activities as well as through natural spread by floods downstream. Inappropriate disposal of aquarium contents have been a source of introduction of aquatic...</td>

</tbody>
</table>

All European biogeographical regions will have the same likelihood of entry and uncertainty scores.

<table>
<thead>
<tr>
<th>Possible pathways</th>
<th>Pathway: Contaminant of leisure equipment (CBD terminology: Transport – stowaway)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Short description explaining why it is considered as a pathway</td>
<td>Consideration can be given to river systems within the EPPO region which are connected to countries outside the EPPO region. It is possible that the use of recreational equipment (e.g. fishing or canoeing gear) could spread the species, particularly as seeds or seedlings, although this is not likely to be significant pathway at present given the rarity of the plant within the EPPO region.</td>
</tr>
<tr>
<td>Is this pathway into the PRA area or within the PRA area or both?</td>
<td>Mainly within the EPPO region, but consideration can be given to river systems within the EPPO region which are connected to countries outside the EPPO region.</td>
</tr>
<tr>
<td>Is the pathway prohibited in the PRA area?</td>
<td>No. However, there are campaigns within the EU to raise awareness of the movement of invasive alien plants by this pathway. For example, the “Check, Clean and Dry” campaign in Great Britain highlights the need to inspect and treat recreational material following use.</td>
</tr>
<tr>
<td>Has the pest already intercepted on the pathway?</td>
<td>No, but this pathway has been highlighted in other countries (Chilton et al., 2002).</td>
</tr>
<tr>
<td>What is the most likely stage associated with the pathway?</td>
<td>Juvenile, seeds and seedlings (Appendix 3; Figure 7).</td>
</tr>
<tr>
<td>What are the important factors for association with the pathway?</td>
<td>Potential to consolidate local or regional populations.</td>
</tr>
<tr>
<td>Is the pest likely to survive transport and storage in this pathway?</td>
<td>Without adequate biosecurity measures the plant could survive in damp equipment (boots, hulls of boats and fishing material for example).</td>
</tr>
<tr>
<td>Can the pest transfer from this pathway to a suitable habitat?</td>
<td>Yes. Where recreational equipment is contaminated, left untreated and then transferred to another region (pond, lake or river for example), plant propagules can transfer to new areas.</td>
</tr>
<tr>
<td>Will the volume of movement along the pathway support entry?</td>
<td>No. Within the EPPO region the current occurrence of P. stratiotes in the wild is low, leading to the probability of movement through this pathway being low.</td>
</tr>
<tr>
<td>Will the frequency of movement along the pathway support entry?</td>
<td>It is unlikely that the frequency of movement by leisure equipment will support entry as the current occurrence of the species within the region is low.</td>
</tr>
</tbody>
</table>
All European biogeographical regions will have the same likelihood of entry and uncertainty scores.

9. Likelihood of establishment in the natural environment in the PRA area

*Pistia stratiotes* spreads mainly asexually by production of daughter plants, which detach from the mother plant (Neuenschwander *et al.*, 2009). Heidbüchel *et al.* (2016) reported that up to 10 000 plants per day during the summer and autumn were introduced into the River Rhine from one of its tributaries, the thermally abnormal River Erft from an established *P. stratiotes* population. Even though the production of viable seeds has been observed in several sites, there is no report of seed germination in the field within the EPPO region (Sajna *et al.*, 2007; Hussner *et al.*, 2014a).

The plants withstand freezing air temperatures, as long as the water temperature does not drop below 10 °C, in a small flat winter form (Hussner *et al.*, 2014a). *P. stratiotes* is established in Morocco and Israel (Dufour-Dror, 2012) and southern France (Fried, pers.com.). An established population of *P. stratiotes* occurs at least one location (where the first observation date back to 2005) in a canal along the Rhône river in the south of France (Fried, com. pers., update 2016).

*P. stratiotes* is able to become established in the climatic zones without frost events, for example Mediterranean and South-western European countries (e.g. Portugal, Spain, Italy, Greece) and in thermal waters in e.g. Slovenia, Germany or Hungary.

According to climate modelling (See appendix 1), *P. stratiotes* is capable of establishing in the Mediterranean biogeographical region. The species is capable of limited establishment in small areas of the Black Sea and Atlantic biogeographical regions (See see appendix 1, Figure 5).

Habitats within the endangered area include slow moving rivers, canals, irrigation and drainage systems, lakes, reservoirs which are widespread within the EPPO region.

</tbody>
</table>

10. Likelihood of establishment in the managed environment in the PRA area

*Pistia stratiotes* is traded and normally established in protected (managed) conditions, for example under glass (Personal observations, EWG). The species can establish in artificial water bodies (hydro-electric power plants, irrigation channels, reservoirs, rice paddies, waste water treatment sites, etc.) (Hussner *et al.*, 2014a, Sajna *et al.*, 2007).

</tr>
</tbody>
</table>
11. Spread in the PRA area

Natural spread
*Pistia stratiotes* spreads mainly asexually by production of daughter plants, which detach from the mother plant (Neuenschwander *et al*., 2009). Heidbüchel *et al*. (2016) reported that up to 10,000 plants per day during the summer and autumn were introduced into the River Rhine from one of its tributaries, the thermally abnormal River Erft from an established *P. stratiotes* population. Even though the production of viable seeds has been observed in several sites, there is no report of seed germination in the field within the EPPO region (Sajna *et al*., 2007; Hussner *et al*., 2014a). However, long distance dispersal of seeds by waterfowl was found to be high likely for other aquatic plants (Green, 2016). Between connecting waterbodies dispersal is via whole plants, though seed dispersal may be possible.

*P. stratiotes* is likely to survive during natural spread in the warmer months of the year, though low temperatures could kill the plant during winter months (MacIsaac *et al*., 2016). With natural spread along water bodies, and by movement by waterfowl, the species is likely to transfer to suitable habitats.

Human assisted spread
Intended and / or unintended movement of plants by people is the most significant pathway of human mediated spread in the EPPO region. *P. stratiotes* is widely cultivated in many botanical gardens in Europe and is widely sold in aquarium and garden shops and is very popular because of its attractive growth form (Hussner *et al*., 2014b). For example:

https://www.amazon.co.uk/Lettuce-Pistia-Stratiotes-Aquarium-Floating/dp/B00CPUXE2O
http://www.lilieswatergardens.co.uk/pistia-stratiotes-british-grown-raised-loose-plants-p-1315.html

Hussner (pers. comm, 2017) noted a large number of *P. stratiotes* plants are offered for sale on online market places like ebay from sellers located in cities along the River Erft (where the species is established and form dense population) indicating the high potential for human intended spread of the species. The spread of plants and seeds attached to water sports equipment seems possible, but evidence is lacking within the EPPO region. But this transport pathway was identified as a potential pathway for other aquatic plants (Barnes *et al*., 2013; Bruckerhoff *et al*., 2015). The likelihood of a species to spread via boats and trailers largely depends on its resistance to desiccation (Barnes *et al*., 2013).

In Belgium an awareness campaign was set up within the LIFE Alterias project where alternative plants are recommended instead of invasive plants to reduce human assisted spread. *P. stratiotes* was specifically envisaged in this campaign (see: http://www.alterias.be/en/list-of-invasive-and-alternative-plants/alternative-plants and Halford *et al*. 2014).

Human assisted spread and the likelihood of transfer to a suitable habitat is moderate within the PRA area (EWG opinion).

Spread will be most likely to occur throughout the endangered area: Mediterranean biogeographical region (Albania, Algeria, France, Greece, Italy, Morocco, Portugal, Spain, Turkey, Tunisia).

A moderate rating of magnitude of spread has been given as potentially spread through irrigation and river systems may act to facilitate spread nationally and regionally. However, this scale of spread has not been seen as yet in the EPPO region and therefore an uncertainty rating of moderate is given.
12. Impact in the current area of distribution

12.01 Impacts on biodiversity and the environment

In general, dense mono-specific growth of any aquatic plant species can incur impacts on native plant communities and other aquatic organisms such as macro and micro invertebrates, fish and waterfowl (Carpenter and Lodge, 1986). This species can completely transform and alter trophic dynamics resulting in long-term changes.

Dense mats of *P. stratiotes* block sunlight, reducing primary production, decreasing water turbidity (Cai 2006 in Neuenschwander *et al*., 2009). Furthermore, the water shaded by *Pistia* shows decreased levels of oxygen and increased levels of nitrate, ammonium and phosphorus (Neuenschwander *et al*., 2009). As a result of the altered habitat, submerged vegetation decreased under dense mats along the river Erft in western Germany (Hussner 2014). Cilliers *et al*. (1996) reported that *P. stratiotes* threatens indigenous flora and fauna in South Africa, while increased mortality rates of fish and macroinvertebrates were reported from the USA (Dray & Center, 2002). In addition, the presence of *P. stratiotes* can increase the rates of siltation which can act to smother and degrade fish spawning sites (Dray and Center, 2002). Besides the blocking of sunlight the *Pistia* mats limit the wind induced mixing of the water column, and thus the water beneath the *Pistia* mats can become thermally stratified (Sculthorpe, 1967; Attionu, 1976), with reduced dissolved oxygen levels and increased alkalinity (Yount, 1963; Attionu, 1976; Sridhar and Sharma, 1985). Finally, Sharma (1984) reported that the evapotranspiration rate over a *P. stratiotes* mat in one African lake was ten-fold greater than the evaporation rate over open water (but see the discussion on this topic and common misconceptions in Allen *et al*., 1997).

To-date there are no impacts recorded on red list species and species listed in the Birds and Habitats Directives.

</tr>
<tr>
<td>Cultural</td>
<td>Yes</td>
<td><em>P. stratiotes</em> can restrict access for recreation and tourism. The species can degrade habitats making them less appealing to the general public and block waterways restricting the transportation of leisure boating. Dense mats restrict access to angling waters.</td>
<td>Chamier et al., 2012</td>
</tr>
</tbody>
</table>

The impacts on ecosystem services detailed in the table above have all been shown to be significant negative impacts within the current area of distribution.

Negative impacts on ecosystem services are hard to assess, given that many descriptions in the literature relate to potential impacts or impacts of sprawling emergent weeds with a similar native range such as *A. philoxeroides* and *Myriophyllum aquaticum* (e.g., Dugdale & Champion, 2012; Hussner & Champion, 2012). However, as an aquatic plant species that can form smothering mats impacts on ecosystem services can be potentially significant. The risk assessment for ecosystem services is therefore given a high rating of magnitude with a low level of uncertainty is given.
12.03. Describe the adverse socio-economic impact of the species in the current area of distribution

**Economic impact**

There are references onto the impact of the species in rice paddies where it is documented as a serious weed (Suasa-Ard, 1979 in Dray & Center, 2002), however, also it is documented as having a positive value on rice yields when used as a soil conditioner (Roger and Watanabe, 1984). Although no accurate measurement is available of the loss of water needed for agriculture through transpiration from beds of *P. stratiotes*, losses are believed to be considerable (Holm et al. 1977). *P. stratiotes* can reduce water flow in drainage and irrigation systems and flood control canals (Dray & Center, 2002), and increase the water loss by evapotranspiration (Sharma 1984, but see Allen et al., 1997 in Neuenschwander et al., 2009 for contrasting results). *P. stratiotes* mats also block water flow and reduce hydropower production (Dray & Center, 2002).

*Pistia stratiotes* may have serious negative effects on the multifunctional human use of water bodies. These harmful effects include impediment of the transport of irrigation and drainage water, interference with hydro-electric schemes from artificial lakes, hindering navigation and fishing and the creation of habitats favourable for the transmittance of water-borne diseases (Mbati and Neuenschwander, 2005).

The dense mats of *P. stratiotes* can provide a suitable habitat for disease-carrying mosquitoes such as *Culex*, *Anopheles* and *Mansonlia* species (Lounibos & Dewald, 1989). This has serious human health implications. Gangstad and Cardarelli (1990) notes that larvae of *Mansonlia* mosquitoes may directly obtain oxygen from the roots of *P. stratiotes*.

The covering of water surfaces interacts with recreational water sports activities, like boating, fishing and swimming. The potential economic impact could be significant if the species establishes and spreads in the EPPO region; especially when consideration is given to the loss of earnings and costs associated with management for other aquatic species. Based on a national survey in France, the cost of water primrose (*Ludwigia* spp.) and waterweed (*Elodea* spp.) were estimated at nearly 8 million euros a year (low estimate) (Chas & Wittmann, 2015). The annual cost of just one such species, *Hydrocotyle ranunculoides* L., to the British economy alone was estimated at €33-million (Williams et al., 2010).

Costs for the control of *P. stratiotes* can be high. Based on annual costs in Florida, associated with controlling *P. stratiotes* on at least 4 000 ha of public waterways, total expenditures exceed $2-million (Center 1994). Other States in the eastern USA spend a combined total less than $100 000 per year on *P. stratiotes* control (Center, 1994). In Florida, the combined total to [maintenance] control *P. stratiotes* and *Eichhornia crassipes* equates to $4 – 5 million a year, over the last 40 years. The cost of developing and maintaining the biological control programme in South Africa (1985 to 2015) was approximately Euro 300 000 (Martin Hill pers comm, 2016.).
13. Potential impact in the PRA area

Impacts in the EPPO area will of course likely be attenuated by climatic suitability, but, in areas where *P. stratiotes* will overwinter and spread, impacts are likely to be similar. For example, many of the impacts on biodiversity relate to ecosystem processes such as decomposition and the alteration of nutrient cycling, which, assuming that *P. stratiotes* is able to reach the levels of abundance required for these impacts to be displayed, this can be assumed to occur in these areas just as much as in the current area of distribution.

Please consider my addition at the summary about shading and prevention of wind induced mixing.

Aquatic free-floating plants are highly opportunistic and have the ability to exploit novel habitats. Other non-native mat forming species have been shown to have high impacts in the PRA area. Ecological impacts occur within the PRA area on flora and fauna, specifically documented for the former in the River Erft in Germany, where floating mats shade out native submerged vegetation.

The potential economic impact of *P. stratiotes* in the EPPO region could be significant if the species spreads and establishes in further areas. There is potential for the species to impede transport and affect recreation, irrigation and drainage. Based on experience elsewhere in the world, management is likely to be both expensive and difficult. There are no indigenous host specific natural enemies in the EPPO region to regulate the pest species, and in many EPPO countries herbicide application in or around water bodies is highly regulated or not permitted.

Even though the EWG considers the magnitude of impacts will be similar to that seen in the current area of distribution, the uncertainty will increase for all categories (impact on biodiversity, impact on ecosystem services and socio-economic impact). This is mainly due to the fact that impacts have not been measured in the PRA area.

In the PRA area, *P. stratiotes* has the potential to impact on native plant species due to its invasive smothering behaviour. The invasion of alien invasive plants can increase competition for space with native aquatic plants and this will affect the most threatened aquatic plant species (Bilz et al., 2011).

In areas where *P. stratiotes* is unable to establish all year round, negative impacts may still be seen in the summer months, including impacts on ecosystem services (cultural: restricting access for recreation and tourism, and supporting: altering the chemical composition of the water column) (EWG opinion). Furthermore, seasonal cover on the waterbody can act to displace native plant species (EWG opinion).

Potential red list species and species from the Habitat Directive which may be impacted on both under current climate and future climate include *Isoetes malinverniana* (Critically Endangered, Italy), *Elatine brochonii* (Vulnerable, France and Spain), *Anagallis crassifolia* and *Marsilea strigosa* (Vulnerable, France, Italy and the Iberian Peninsula), *Plularia minuta* (Endangered), *Damasonium polyspermum* and *Ipomoea sagittata* (Vulnerable).

Within the EPPO region, *P. stratiotes* can negatively impact on freshwater bodies such as canals, rivers (slow moving), ponds, irrigation channels, estuaries, reservoirs and lakes. Many freshwater bodies and wetland sites are protected within the EPPO region. Freshwater habitats are detailed within the Habitats Directive 1992 and the Water Framework Directive 2000. Such habitats often harbour rare or endangered species. Protected sites potentially impacted on are detailed in section 7.
Dense mats of *P. stratiotes* can provide a suitable habitat for disease-carrying mosquitoes which may have impacts on human health (EWG opinion).

The text within this section relates equally to EU Member States and non-EU Member States in the EPPO region.

**Will impacts be largely the same as in the current area of distribution? Yes (in part)**

**14. Identification of the endangered area**

*Pistia stratiotes* is a frost sensitive free-floating species. The southern countries within the EPPO region provide suitable climatic conditions for *P. stratiotes*. All water bodies not enclosed in freezing during the winter months, including thermally abnormal waters in other EPPO countries, provide potential habitats for *P. stratiotes*.

*Pistia stratiotes* is capable of establishing in the Mediterranean biogeographical region. The species is capable of limited establishment in small areas of the Black Sea and Atlantic biogeographical regions (see appendix 1, Figure 5 and Appendix 2, Figure 1).

Significant impact could be expected in man-made water bodies.

Habitats within the endangered area include slow moving rivers, canals, irrigation and drainage systems, lakes and reservoirs which are widespread within the EPPO region.

**15. Climate change**

**Climate change**

By the 2070s, under climate change scenario RCP8.5, the projected suitability for *P. stratiotes* in Europe and the Mediterranean increased substantially. The model suggested that in this climate, much of Mediterranean, western and Pannonian Europe could become suitable for invasion, and suitability also increases around the coasts of the Black Sea and Caspian Sea. Therefore, the model suggests climate change could facilitate a major expansion of the species in Europe. Countries suitable include Portugal, Spain, France, Italy, Greece, Belgium, Netherlands, Slovenia, Croatia, Turkey, Bulgaria, Germany, Russia (coast of the Black Sea), Algeria, Morocco, Tunisia.
15.01. Define which climate projection you are using from 2050 to 2100*
Climate projection: **RCP 8.5 (2070)**

**Note:** RCP8.5 is the most extreme of the RCP scenarios, and may therefore represent the worst-case scenario for reasonably anticipated climate change.

15.02 Which component of climate change do you think is most relevant for this organism? Delete (yes/no) as appropriate

Are the **introduction pathways** likely to change due to climate change? *(If yes, provide a new risk and uncertainty score)*

The introduction pathways are unlikely to change as a result of climatic change as the species enters the EPPO region as a result of the horticultural trade.

The overall rating for introduction pathways will not change.

**Reference**

Hussner *et al.*, 2014b

Is the **risk of establishment** likely to change due to climate change? *(If yes, provide a new risk and uncertainty score)*

The risk of establishment in some countries will increase with increasing temperature where frost events currently hinder *P. stratiotes* establishment. With projected climate change it is predicted (using the scenario RCP 8.5: 2070) that the species will be capable of establishing throughout the Atlantic zone, Western Continental Europe, and is likely to increase its potential distribution in North Africa (see appendix 1, Figure 6).

The overall rating given in section 9 and 10 will not change.

**Reference**

See appendix 1. Pieterse *et al.*, 1981; Sajna *et al.*, 2007; Hussner *et al.*, 2014a

Is the **risk of spread** likely to change due to climate change? *(If yes, provide a new risk and uncertainty score)*

The risk of spread into countries from interconnecting water bodies, in which frost events currently hinder *P. stratiotes* to become established, will increase with increasing temperature.

Increased flood events resultant of climate change could facilitate the spread of the species into new regions (see appendix 1, Figure 6).

The risk of spread will remain as moderate but the level of uncertainty could be reduced from moderate to low.

**Reference**

Pieterse *et al.*, 1981; Sajna *et al.*, 2007; Hussner *et al.*, 2014a

Will **impacts** change due to climate change? *(If yes, provide a new risk and uncertainty score)*

With increasing temperature, the impacts of *P. stratiotes* will be more profound than under the current climatic conditions. As the species spreads impacts will manifest across a larger part of the PRA area. More rapid growth and biomass accumulation will result in higher impacts to native species.

The overall rating given in section 12 will not change.

**Reference**

16. Overall assessment of risk

The overall likelihood of *P. stratiotes* entering into the EPPO region is high. The plant is imported into the EPPO region under its proper name and sold for aquarium and garden ponds. In addition, it is grown and traded within the EPPO region.

In view of risk of entry, risk of establishment and risk of spread, it is surprising, despite the long history of trade as an ornamental, and the climatic match with the Mediterranean, it is not yet widely established. However, where it has become established in Morocco it is a serious pest.

*Pistia stratiotes* has already been reported as a casual in Austria, Belgium, Croatia, Czech Republic, parts of France, Germany, Hungary, Norway, Italy, The Netherlands, Portugal, Romania, Russia, Slovenia, Spain and the United Kingdom. In addition, the species is established in Morocco and Israel. The species is established in Germany, Russia and Slovenia in thermally abnormal waters. At least one established population in southern France shows an invasive behaviour with a canal colonized with 100% cover on nearly 1 km.

### 17. Uncertainty

**Overall uncertainty for the PRA:** Moderate
Currently the species is not invasive in natural habitats in the PRA area, apart from Morocco. However, in view of the overwhelming evidence from elsewhere in the world it is likely to exhibit a similar behaviour in the endangered area.

Uncertainty should also be considered in the context of species distribution modelling (SDM). Here records for *P. stratiotes* and synonyms were retrieved from GBIF and other online sources, and were also digitised from occurrences that were either mapped or clearly georeferenced in published sources. This may mean that the realised climatic niche of *P. stratiotes* is under-characterised. In addition, georeferenced records used in our SDMs were usually without information on population persistence – if records within the EPPO area, or in climatically similar areas, are typically of ‘casual’ occurrences, rather than established populations, it may be that our SDMs over-emphasise the likelihood of establishment in climatically marginal habitats.

To remove spatial recording biases, the selection of the background sample was weighted by the density of Tracheophyte records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, a number of factors mean this may not be the perfect null model for species occurrence:

- The GBIF API query used to did not appear to give completely accurate results. For example, in a small number of cases, GBIF indicated no Tracheophyte records in grid cells in which it also yielded records of the focal species.
- We located additional data sources to GBIF, which may have been from regions without GBIF records.
- Levels of Tracheophyte recording may not be a consistent indicator of the recording of aquatic plants. There is a suggestion that aquatic plants may be disproportionately under-recorded in tropical regions (Jonathan Newman, *pers. comm*), which could have caused an under-prediction of suitability in tropical regions.

Air temperatures were used in the model, while water temperatures may be more appropriate for an aquatic plant. In some cases air and water temperatures can markedly diverge, for example warming associated with industrial outflows. Wherever the water temperature is warm enough, the species is likely to be able to persist, regardless of the model’s estimate of suitability.

Water chemistry and quality may have a large effect on the ability of the species to persist but were not used in the model. Factors such as water pH and nutrient concentration are likely to be important modifiers of habitat suitability.

The climate change scenario used is the most extreme of the four RCPs. However, it is also the most consistent with recent emissions trends and could be seen as worst-case scenario for informing risk assessment.

The EWG acknowledge that the model may underestimate the potential suitability for the EPPO region based on the points detailed above. This is highlighted by the occurrence of an established population in the south of France.

**Level of uncertainty per sections:**

Pathway for entry: Low
Likelihood of establishment:
Establishment in natural areas: Moderate
Establishment in managed areas: Low
Spread: Moderate
Impacts: Low
Potential impacts in PRA area: High

18. Remarks
Other recommendations:
Inform EPPO or IPPC or EU
- Inform NPPO’s, that surveys are needed to confirm the distribution of the plant, in particular in the area where the plant is present on the priority to eradicate the species from the invaded area.

Inform industry, other stakeholders
- Encourage industry to assist with public education campaigns associated with the risk of aquatic non-native plants.

Specify if surveys are recommended to confirm the pest status
Surveys should be conducted to confirm the current distribution and status of the species within the endangered area and this information should be shared within the PRA area

Appendix 1. Projection of climatic suitability for *P. stratiotes* establishment

**Aim**

To project the suitability for potential establishment of *Pistia stratiotes* in the EPPO region, under current and predicted future climatic conditions.

**Data for modelling**

Climate data were taken from ‘Bioclim’ variables contained within the WorldClim database ([http://www.worldclim.org/](http://www.worldclim.org/)), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) but bilinearly interpolated to a 0.1 x 0.1 degree grid for use in the model. Based on the biology of the focal species, the following variables were used in the modelling:

- Mean temperature of the warmest quarter (Bio10 °C) reflecting the growing season thermal regime. As described in the main text, cold temperatures are known to limit growth of *P. stratiotes*.
- Mean minimum temperature of the coldest month (Bio6 °C) reflecting exposure to frost. *Pistia stratiotes* is known to be highly sensitive to frosts and freezing of the water surface.
- Precipitation of the warmest quarter (Bio18 ln+1 transformed mm). Although the species is aquatic and will therefore have limited direct dependence on precipitation, seasonal drying out of waterbodies may reduce suitability. We anticipate this to be more common when the warmest quarter has low precipitation.

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathway (RCP) 8.5 were also obtained. This assumes an increase in atmospheric CO₂ concentrations to approximately 850 ppm by the 2070s. Climate models suggest this would result in an increase in global mean temperatures of 3.7 °C by the end of the 21st century. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline ([see http://www.worldclim.org/cmip5_5m](http://www.worldclim.org/cmip5_5m)). RCP8.5 is the most extreme of the RCP scenarios, and may therefore represent the worst case scenario for reasonably anticipated climate change.

As a measure of habitat availability, we used the Global Inland Water database provided by the Global Land Cover Facility ([http://elcfapp.glcf.umd.edu/data/watercover/](http://elcfapp.glcf.umd.edu/data/watercover/)). The original database is a remote sensed estimate at a 30 x 30 m resolution of the presence of inland surface water bodies, including fresh and saline lakes, rivers, and reservoirs. For the PRA, this was supplied as a 0.1 x 0.1 degree raster indicating the proportion of the constituent 30 x 30 m grid cells classified as inland waters.

Species occurrences were obtained from the Global Biodiversity Information Facility ([www.gbif.org](http://www.gbif.org)), supplemented with data from the literature and the Expert Working Group. Occurrence records with insufficient spatial precision, potential errors or that were outside of the coverage of the predictor layers (e.g. small island or coastal occurrences) were excluded. The remaining records were gridded at a 0.1 x 0.1 degree resolution (Figure 1).

Examination of these records by the Expert Working Group indicated a number were either examples of casual occurrences introduced to climatically unsuitable regions (for example, where winter frosts are known to kill all individuals) or records of persistent populations known to occupy climatically anomalous micro-habitats such as thermal streams or warmed industrial outflows. These were removed from the occurrence data as they will impede the model’s ability to characterise climatic suitability. Based on guidance from the Expert Working Group, occurrences were removed based on the following rules for determining high environmental unsuitability (Figure 1):
• Mean temperature of the warmest quarter < 10 °C (below the minimum growth temperature); OR
• Mean minimum temperature of the coldest month < 0 °C (prolonged exposure to lethal frosts); OR
• Precipitation of the warmest quarter < 5 mm AND proportion cover of inland waters == 0 (only small and seasonally dry habitat is available, which is expected to be of low suitability).

In total, there were 1087 grid cells with recorded occurrence of *P. stratiotes* available for the modelling and a further 99 records from regions considered unsuitable and excluded (Figure 1).

**Figure 1.** Map with points showing the occurrence records obtained for *Pistia stratiotes*. The background shading indicates regions considered highly unsuited to *P. stratiotes*. Records found within this region (black circles) were considered to represent casual occurrences or establishment in thermally abnormal microclimates, and were excluded from the modelling.

Species distribution model
A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package v3.3-7 ([https://cran.r-project.org/web/packages/biomod2/index.html](https://cran.r-project.org/web/packages/biomod2/index.html)). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed ‘pseudo-absences’) in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species’ distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to. Therefore the background sampling region included:

• The native continent of *P. stratiotes*, for which the species is likely to have had sufficient time to cross all biogeographical barriers. Although there is some debate about the precise native range, the consensus view of the Expert Working Group was that South America should be used as the native continent; AND
• A relatively small 50 km buffer around all non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
• Regions where we have an *a priori* expectation of high unsuitability for the species, defined using the abovementioned rules (see Figure 1).
Within this sampling region there are likely to be substantial spatial biases in recording effort, which may interfere with the characterisation of habitat suitability. Specifically, areas with a large amount of recording effort will appear more suitable than those without much recording, regardless of the underlying suitability for occurrence. Therefore, a measure of vascular plant recording effort was made by querying the Global Biodiversity Information Facility application programming interface (API) for the number of phylum Tracheophyta records in each 0.1 x 0.1 degree grid cell. The sampling of background grid cells was then weighted in proportion to the Tracheophyte recording density. Assuming Tracheophyte recording density is proportional to recording effort for the focal species, this is an appropriate null model for the species’ occurrence.

To sample as much of the background environment as possible, without overloading the models with too many pseudo-absences, five background samples of 10,000 randomly chosen grid cells were obtained (Figure 2).

**Figure 2.** Randomly selected background grid cells used in the modelling of *Pistia stratiotes.*

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, ten statistical algorithms were fitted with the default BIOMOD2 settings, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline.
- Classification tree algorithm (CTA)
- Artificial neural network (ANN)
- Flexible discriminant analysis (FDA)
- Multivariate adaptive regression splines (MARS)
- Random forest (RF)
- MaxEnt
- Maximum entropy multinomial logistic regression (MEMLR)

Since the background sample was much larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Variable importances were assessed and variable response functions were produced using BIOMOD2’s default procedure. Model predictive performance was assessed by calculating the Area Under the Receiver-Operator Curve (AUC) for model predictions on the evaluation
data, that were reserved from model fitting. AUC can be interpreted as the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence. This information was used to combine the predictions of the different algorithms to produce ensemble projections of the model. For this, the three algorithms with the lowest AUC were first rejected and then predictions of the remaining seven algorithms were averaged, weighted by their AUC. Ensemble projections were made for each dataset and then averaged to give an overall suitability.

Results
The ensemble model had a better predictive ability than any individual algorithm and suggested that suitability for *P. stratiotes* was most strongly determined by the minimum temperature of the coldest month and mean temperature of the warmest quarter (Table 1). The response plots show that the ensemble model estimated biologically reasonable curves, with suitability limited by harsh frosts, low growing season temperatures, low cover of large water bodies and low precipitation in the growing season (Figure 3).

Table 1. Summary of the cross-validation predictive performance (AUC) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing seven algorithms). Results are the average from models fitted to five different background samples of the data.

Figure 3. Partial response plots from the fitted models. Thin coloured lines show responses from the seven algorithms, while the thick black line is the response of their ensemble. In each plot, other model variables are held at their median value in the training data.

The projection of the model indicated high suitability throughout the tropical and subtropical parts of the world (Fig. 4). This was consistent with the observed occurrences of the species in its native and non-native ranges.

In Europe and the Mediterranean, areas projected as currently moderately suitable for establishment included southern Spain and Portugal and the coastal fringes of Morocco, Algeria and Tunisia (Fig. 5). There were also pockets of projected suitability around the coastlines of the Mediterranean and southern Caspian Sea. Occurrences of the species in western Europe that were not excluded from the modelling were projected as being in moderately unsuitable conditions. The status of these populations is unclear but it is likely that they are casual rather than fully established.

By the 2070s, under climate change scenario RCP8.5, the projected suitability for *P. stratiotes* in Europe and the Mediterranean increased substantially. The model suggested that in this climate, much of Mediterranean, western and Pannonian Europe could become suitable for invasion, and suitability also increases around the coasts of the Black Sea and Caspian Sea. Therefore, the model suggests climate change could facilitate a major expansion of the species in Europe.
Figure 4. Global projected suitability for *Pistia stratiotes* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. The white areas have climatic conditions outside the range of the training data so were excluded from the projection. Points show the known occurrences.
Figure 5. Projected current suitability for *Pistia stratiotes* establishment in Europe and the Mediterranean region. To aid visualisation, the projected suitability has been smoothed with a Gaussian filter with standard deviation of 0.1 degrees longitude/latitude. The white areas have climatic conditions outside the range of the training data so were excluded from the projection. Points show the known occurrences used in the modelling.

Figure 6. Projected suitability for *Pistia stratiotes* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP8.5, equivalent to Fig. 5.

**Caveats on the modelling**
To remove spatial recording biases, the selection of the background sample was weighted by the density of Tracheophyte records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, a number of factors mean this may not be the perfect null model for species occurrence:
• The GBIF API query used to did not appear to give completely accurate results. For example, in a small number of cases, GBIF indicated no Tracheophyte records in grid cells in which it also yielded records of the focal species.
• We located additional data sources to GBIF, which may have been from regions without GBIF records.
• Levels of Tracheophyte recording may not be a consistent indicator of the recording of aquatic plants. There is a suggestion that aquatic plants may be disproportionately under-recorded in tropical regions (Jonathan Newman, *pers. comm*), which could have caused an under-prediction of suitability in tropical regions.

Air temperatures were used in the model, while water temperatures may be more appropriate for an aquatic plant. In some cases air and water temperatures can markedly diverge, for example warming associated with industrial outflows. Wherever the water temperature is warm enough, the species is likely to be able to persist, regardless of the model’s estimate of suitability.

Water chemistry and quality may have a large effect on the ability of the species to persist but were not used in the model. Factors such as water pH and nutrient concentration are likely to be important modifiers of habitat suitability.

The climate change scenario used is the most extreme of the four RCPs. However, it is also the most consistent with recent emissions trends and could be seen as worst case scenario for informing risk assessment.
